DEFINITION

“stress” may be considered as the psychological, behavioural and physiological (or pathophysiological) consequence of the interaction between a subject and a stressor; considering as “stressor” everything (acute or chronic) present in the environment or in the subject's mind that could be perceived as important, dangerous or potentially capable to modify, both negatively or positively, the subject's life

Fig. 1. Model of stress (adapted from [2]) and functional syndromes. The effects of stressors on health depend on hypothalamic–pituitary–adrenal (PHA) axis, autonomic nervous system (ANS) and immunity responses mediated by central nervous system (CNS), individual stress perception, individual differences and behavior. The final result may be adaptation or maladaptation represented by negative organic (somatic symptoms or increased risk of disease) and/or psychosocial consequences. These latter ones may per se become new stressors initiating a vicious cycle.

STRESS

Management program

Ecological approach

Table 1 Different elements of the Health programs of companies A and B

	Company A	Company B
<i>Medical screening</i>		
Medical history	Y	Y
Physical examination	Y	Y
Biochemical	Y	Y
Internist health consultation	N	Y
<i>Web tool</i>		
General info on healthy lifestyle	Y	Y
Lifestyle questionnaire (diet, exercise, stress)	Y	Y
Personalized suggestions	Y	Y
<i>Nutrition</i>		
General information	Y	Y
Special healthy canteen	N	Y
<i>Exercise</i>		
General information	Y	Y
Gym	N	Y
Tailored programs	N	Y
Physical activity assessment (accelerometer)	N	Y
Outdoor running track	N	Y
<i>Wellness fostering service</i>		
Web tutorial (nutrition, exercise, stress)	Y	Y
Group meeting (nutrition, exercise, stress)	N	Y

The specific attention to personal, organizational and environment aspects connotes the program of company B as ecological

Y = present

N = absent

The physical examination provided information on anthropometrics (height, weight, waist circumference), and cardiovascular (heart rate, arterial pressure) individual values. Biochemical data were obtained by way of standard test from blood samples in a laboratory of participants' choosing, or one offered by either company. Numerical data were entered in the web tool by participants. Potential advantages and disadvantages in the context of MetS have been discussed already [10]

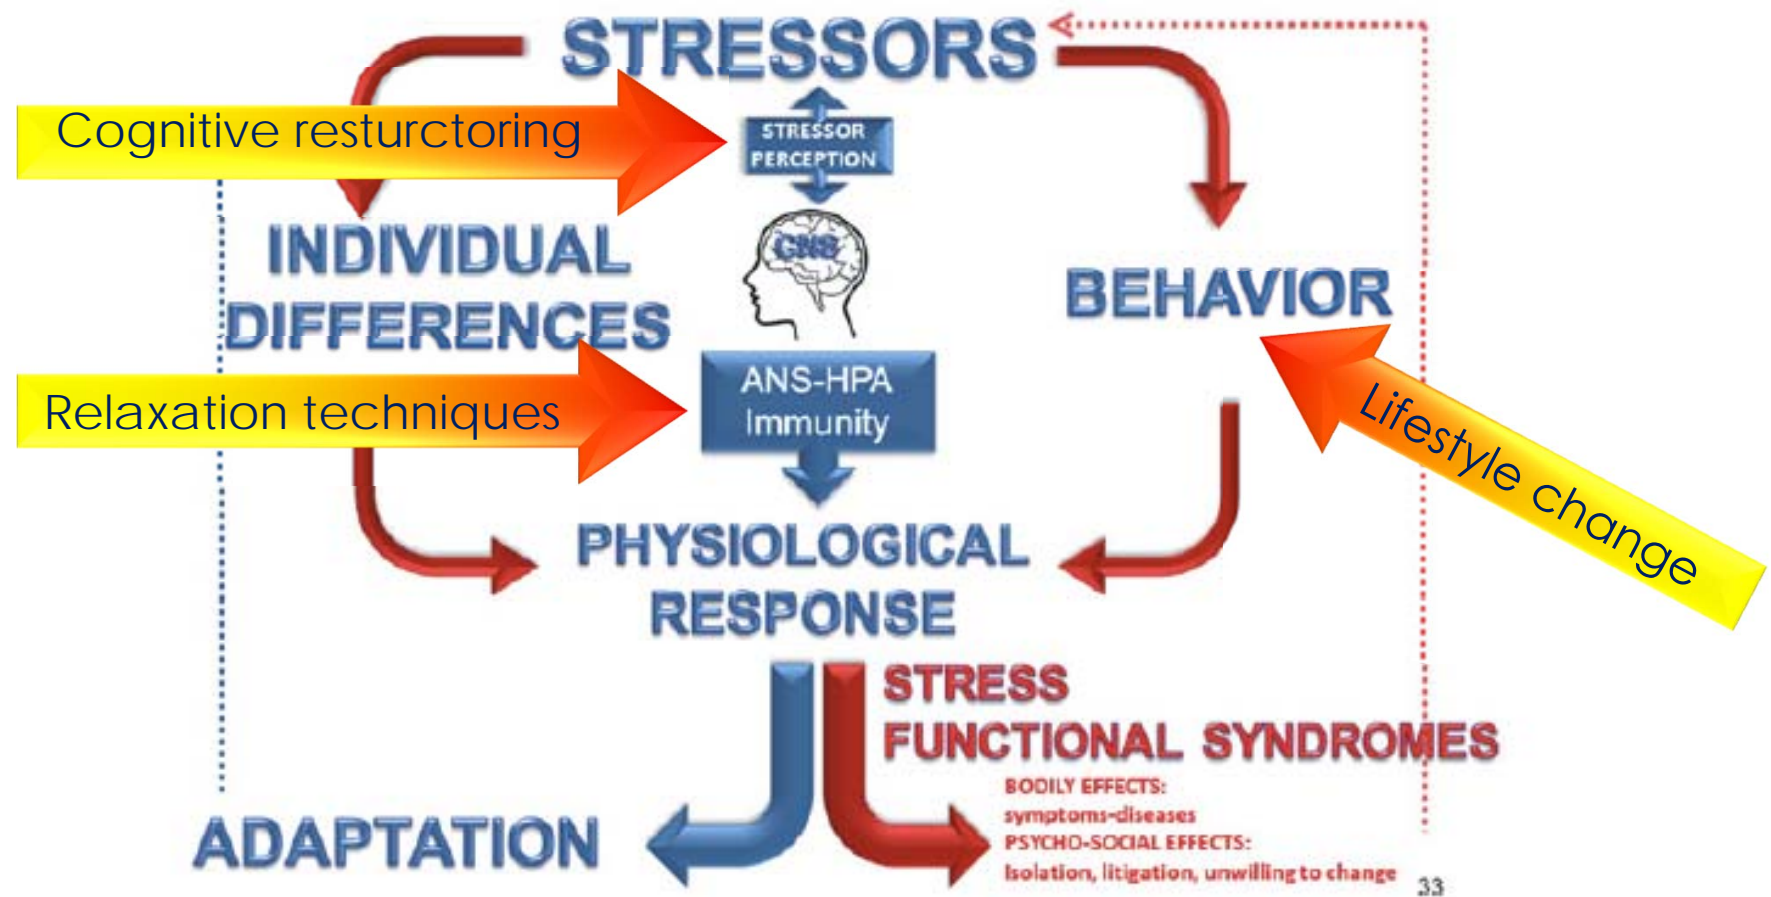

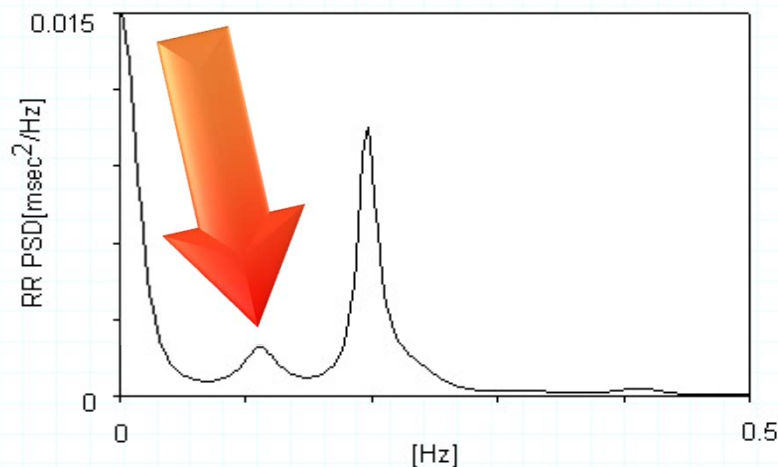

Fig. 1. Model of stress (adapted from [2]) and functional syndromes. The effects of stressors on health depend on hypothalamic–pituitary–adrenal (PHA) axis, autonomic nervous system (ANS) and immunity responses mediated by central nervous system (CNS), individual stress perception, individual differences and behavior. The final result may be adaptation or maladaptation represented by negative organic (somatic symptoms or increased risk of disease) and/or psychosocial consequences. These latter ones may per se become new stressors initiating a vicious cycle.

CONTROL

MENTAL RELAXATION

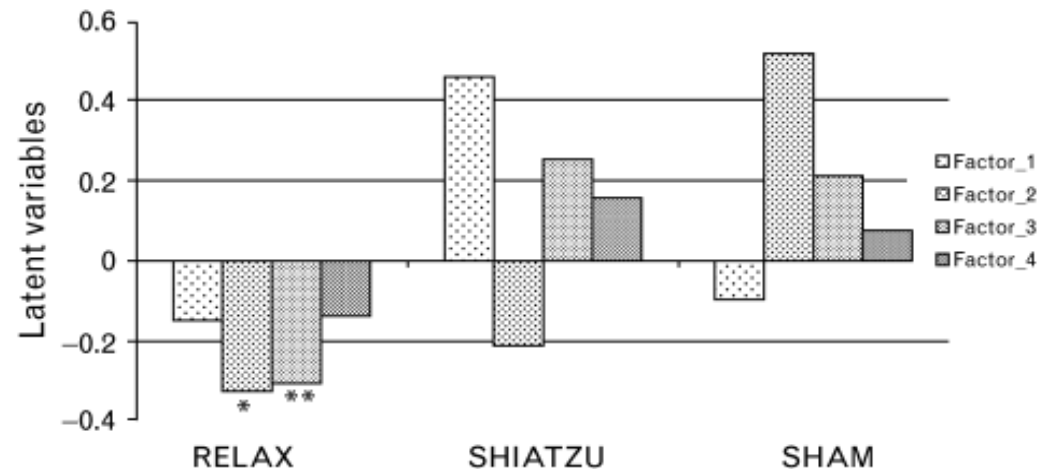

Complementary medicine for the management of chronic stress: superiority of active versus passive techniques

Daniela Lucini^a, Mara Malacarne^a, Nadia Solaro^b, Silvano Busin^c and Massimo Pagani^a

MENTAL RELAXATION

Treatment groups

Results of factor analysis on the effects of different stress treatments, comparing active (relax), passive (shiatsu) and sham modalities. Notice that only the relaxation group shows a clear reduction in factors 2 (psychological stress perception) and 3 (normalized autonomic oscillatory indices). No difference is present in factor 1 (absolute autonomic indices) and factor 4 (heart rate and respiration). Significance * $P < 0.05$; ** $P < 0.01$.

Reducing the risk of metabolic syndrome at the worksite: preliminary experience with an ecological approach

Daniela Lucini^{1,2} · Silvano Zanuso^{3,4} · Nadia Solaro⁵ · Chiara Vigo^{1,2} · Mara Malacarne^{1,2} · Massimo Pagani¹

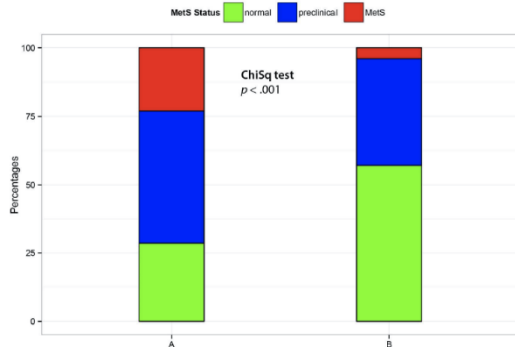

The study involved 1089 workers of two Italian multinational companies (683 in company A and 406 in company B) that follow different workplace health promotion policies.

LIFESTYLE

The Company (B) which offers an environment and culture that promote healthy lifestyle, has an higher number of employees without (or 1-2) metabolic syndrome components as compared to company A which does not guarantee this ecological approach

MetS Status ■ normal ■ preclinical ■ MetS

INDIVIDUAL PROBABILITY

Normal

Preclinical

MetS

Table 4 Model-based individual probabilities (IP) of being within a specific MetS status computed by companies and controlling for gender and age group

Individual Probability of being without MetS components is higher in Company B which offers an environment and culture that promote healthy lifestyle

Gender	Age group	Company	N	IP normal ^a	IP preclinical ^a	IP MetS ^a	Sum
Female	<35	A	26	0.698	0.297	0.005	1
		B	37	0.883	0.116	0.001	1
	35–44	A	58	0.582	0.411	0.007	1
		B	81	0.819	0.179	0.002	1
	>44	A	104	0.556	0.429	0.015	1
		B	15	0.804	0.192	0.004	1
Male	<35	A	55	0.257	0.584	0.159	1
		B	93	0.530	0.423	0.047	1
	35–44	A	133	0.172	0.611	0.217	1
		B	130	0.404	0.529	0.067	1
	>44	A	307	0.158	0.489	0.353	1
		B	50	0.379	0.497	0.124	1
Mean probability			1089	0.392	0.454	0.154	1

^a For fixed gender and age group categories, gray-colored cells indicate the largest probability, in the comparison between companies A and B, of being in a specific MetS status. By construction, individual probabilities sum to 1 within each row

$P < 0.006$

- > 40 hours/year
- 1 - 40 hours/year
- 0 hours/year

Correlation Health Index and
absenteeism: $p = 0.024$

Using a unitary health index (HI) from self-reports, poor health behavior is associated with more elements of metabolic syndrome and with fewer elements of the ideal cardiovascular health profile.

HEALTH METRICS COMPONENTS

A composite autonomic index as unitary metric for heart rate variability: a proof of concept

Roberto Sala^{*,†}, Mara Malacarne^{*,†}, Nadia Solaro[‡], Massimo Pagani^{*} and Daniela Lucini^{*,†} 

ANSI does not evaluate underlying neural activity, but quantifies the ANS impairment associated with different clinical conditions (hypertension, obesity, smoking), and the greater impact of their combination if simultaneously present in the same subject. As cardio-metabolic risk factors increase, greater is the impairment of ANS regulation.

Figure 2 The bar plot of the means of ANSI₃ percentiles computed for each group formed by combinations of SAP, BMI and smoking categories. Overall, reduced ANSI values against reference normal group, indicative of impaired autonomic performance, are observed in groups with poor clinical profile, as approximated by clustering of elevated SAP and BMI, and of smoking. One-sided Dunnett's test to verify equality of within-group ANSI means against ANSI means lower than control group. Symbols for clinical conditions: SAP categories with thresholds at 120 and 140 mmHg are -, +, ++; BMI categories with thresholds at 25 and 30 kg/m² are -, +, ++; SMOKING is dichotomized into no/yes corresponding to - or +. A group with only 5 subjects (+, ++, +) is not considered. **P* < 0.02.

A composite autonomic index as unitary metric for heart rate variability: a proof of concept

Roberto Sala^{*,†}, Mara Malacarne^{*,†}, Nadia Solaro[‡], Massimo Pagani^{*} and Daniela Lucini^{*,†} 

ANSI

Autonomic Nervous System Index

A composite unitary Autonomic Nervous System Index of cardiac regulation (expressed in percentile rank [reference population, n=1593, age 39±13 yrs]) is a possible way to integrate the partial information spread across multiple autonomic variables and represents a proxy of *quality* of autonomic regulation against a benchmark population. It, considering both static and oscillatory information embedded in HRV, is capable of detecting the graded changes in cardiac neural regulation occurring along the continuum from dysfunction in patients to improvement in endurance athletes, and might be part of a therapeutic or preventive programs, such as in the emerging field of personalized medicine

Figure 3 Schematic representation of the position of the mean value of percentile rank for the various groups (left) and projected mean values of tests groups (elite endurance, diabetes type 1, diabetes type 2, coronary artery disease, CAD). Significance of differences against normal (reference population of controls) is indicated in the bottom left panel (Dunnett's test). A 0–100 reference scale (white) is provided in the bar.
